

## DECLARATION

I, Yoshiaki ITO, having an address of 2nd Floor, Park Shiba-Building, 2-17-11 Shiba, Minato-ku, Tokyo 105-0014 Japan, hereby declare that I have competent knowledge of the Japanese and English languages, and that I have made the English translation of Japanese Patent Application No. 2003-340921 filed on September 30, 2003 and that said translation is true and correct to the best of my knowledge and belief.

DECLARED by Yoshiaki ITO

at 2nd Floor, Park Shiba-Building, 2-17-11 Shiba, Minato-ku, Tokyo 105-0014 Japan

This 11th day of August , 2009

Yoshiaki ITO

[List of Documents Attached]

[Document] Claims 1

[Document] Specification 1

[Document] Drawing(s) 1

[Document] Abstract Sheet 1

[Number of General Power of Attorney] 9102133

[Name of Document] Claims

[Claim 1] An optical recording medium, characterized by comprising:

a data recording layer on which contents data is recorded by irradiation of an optical beam, and

a visual information recording layer on which visual information which is visually recognized and indicative of information regarding the contents of the contents data is recorded by irradiation of the optical beam,

wherein the data recording layer and the visual information recording layer are laminated.

[Claim 2] The optical recording medium according to claim 1, characterized in that the visual information is visually recognized from a surface different from a data recording surface which is a surface through which the data recording layer is irradiated with the optical beam and is recorded on the visual information recording layer by irradiation of the optical beam.

[Claim 3] The optical recording medium according to claim 1 or 2,

characterized in that the visual information is recorded on the visual information recording layer by irradiation of the optical beam from the surface different from the data recording surface.

[Claim 4] The optical recording medium according to any one of claims 1 to 3,

characterized in that the data recording layer is provided on a first substrate, and the visual information area is provided on a second substrate.

[Claim 5] The optical recording medium according to any one of claims 1 to 4,

characterized in that the visual information recording layer has a visual information area for recording the visual information, and a visual information management area in which at least one of recording layer information indicative that the recording layer is the visual information recording layer, recording management information indicative of presence or absence of a record of the visual information, an area information indicative of a recordable area of visual information, and contents information indicative of the contents of the visual information are recorded.

[Claim 6] The optical recording medium according to any one of claims 1 to 5,

characterized in that the visual information recording layer has a visual information area on which the recording layer information indicative that the recording layer is the visual information recording layer is regularly recorded.

[Claim 7] The optical recording medium according to any one

of claims 1 to 6,

characterized in that the data recording layer has a data recording area for recording the contents data, and a data management area in which at least one of the recording layer information indicative that the recording layer is the data recording layer, and recording medium information indicative that the visual information recording layer is provided on the optical recording medium is recorded.

[Claim 8] The optical recording medium according to claim 7,

characterized in that the data recording layer has the data management area in which at least one of recording management information indicative of the presence or absence of the record of the visual information, and the area information indicative of the recordable area for visual information is recorded.

[Claim 9] A data recording apparatus that records visual information onto an optical recording medium formed by lamination of a data recording layer onto which contents data is recorded, and a visual information recording layer on which visual information which is visually recognized and indicative of information regarding the contents of the contents data is recorded,

the data recording apparatus being characterized by comprising:

an interface that inputs the visual information to be recorded;

a pickup that is used to record the input visual information; and

a visual-information dedicated drive signal generating device that generates a visual-information dedicated drive signal for driving the pickup in accordance with the input visual information,

wherein the pickup records the visual information onto the visual information recording layer in accordance with the generated visual-information dedicated drive signal.

[Claim 10] The data recording apparatus according to claim 9, comprising:

a contents-data dedicated drive signal generating device that, when the contents data is input into the interface, and the pickup records the contents data onto the data recording layer, generates a contents-data dedicated drive signal for driving the pickup in accordance with the input contents data; and

a selecting device that selects one of the generated contents-data dedicated drive signal and the visual-information dedicated drive signal generated by the visual-information dedicated drive signal generating device,

wherein, when the contents-data dedicated drive signal is selected, the pickup records the contents data onto the data recording layer in accordance with the selected contents-data dedicated drive signal; and when the visual-information dedicated drive signal is selected, the pickup records the

contents data onto the data recording layer in accordance with the selected visual-information dedicated drive signal.

[Claim 11] The data recording apparatus according to claim 9, comprising:

a contents-data dedicated drive signal generating device that, when the contents data is input into the interface, generates a contents-data dedicated drive signal for driving the pickup in accordance with the input contents data; and

a data recording pickup that is different from a visual-information recording pickup which is the pickup for recording the visual information, and that records the contents data onto the data recording layer in accordance with the visual-information dedicated drive signal generated by the contents-data dedicated drive signal.

{Claim 12} The data recording apparatus according to claim 11, characterized in that the visual-information recording pickup records the visual information with a diameter of an optical beam that is greater than a diameter of an optical beams generated by the data recording pickup.

[Claim 13] The data recording apparatus according to claim 12, characterized in that the visual-information recording pickup has an NA (numerical aperture) lower than that of the data recording pickup.

[Claim 14] The data recording apparatus according to claim 12, characterized in that the visual-information recording pickup emanates an optical beam having a longer wavelength than the data recording pickup.

[Claim 15] The data recording layer according to any one of claims 10 to 14, characterized by comprising:

a detecting device that detects at least one of the recording layer information recorded in the recording management area of the visual information recording layer, and the recording layer information recorded in the visual information area of the visual information recording layer; and

a determining device that determines an irradiation surface of the optical recording medium being irradiated with the optical beam in accordance with the detection result of the detecting device,

in the case where the optical recording medium includes a visual information recording layer having at least one of a recording management area in which the visual information is recorded by irradiation of the optical beam from the surface different from the data recording surface and wherein at least recording layer information indicative that the recording layer is the visual information recording layer is recorded, and a visual information area in which the visual information and recording layer information indicative that the recording layer is the visual information recording area is recorded.

[Claim 16] The data recording apparatus according to claim 15,  
characterized by comprising:

a detecting device that detects the recording layer  
information recorded in the data management area of the data  
recording layer; and

a determining device that determines an irradiation  
surface of the optical recording medium being irradiated with  
the optical beam in accordance with the detection result of the  
detecting device,

in the case where the optical recording medium includes  
the visual information recording layer in which the visual  
information is recorded by irradiation of the optical beam from  
the surface different from the data recording surface, and the  
data recording layer having the data management area in which  
at least the recording layer information indicative that the  
recording layer is the data recording layer is recorded.

[Name of Document] Specification

[Title of the Invention] Optical recording Medium and Data Recording Apparatus

[Technical Field]

[0001]

The present invention fall into a technical field of optical recording media that record visual information on a surface different from a recording surface to record contents data.

[Background Art]

[0002]

In recent years, as disk-shaped information recording mediums capable of high density information recording, so-called DVD (digital versatile disc) devices are generalized. In addition, data-writable DVD devices, such as DVD-R (DVD-Recordable) devices capable of only one time recording, and DVD-RW (DVD-Rerecordable) devices capable of multi-time rewriting are used in practical application.

[0003]

Conventionally, in the case of optical disks, such as writable optical disks, it is known that in the event of recording contents data, the contents of the recorded contents data, a title thereof, and the like are printed or written by an inkjet printer or handwriting on a surface ("label surface", hereafter)

of an optical disk different from a surface ("data recording surface", hereafter) bearing the recorded contents data for identification of the disk from other optical disks or for indicating the recorded contents.

[0004]

In addition, recently, in the case of such writable optical disks, it is known that the contents of contents data, a title thereof, and the like are recorded as visual information onto a free area of the data recording surface by using a laser beam or laser light.

[0005]

In the case of DVD devices of the type recording the contents of contents data on the data recording surface, an irradiation portion and a non-irradiation portion of laser light are formed on the data recording surface. The laser light irradiation portion and the non-irradiation portion cause variations in optical characteristics to thereby record the visual information (see Patent Document 1, for example).

[Patent Document 1] Japanese Patent Application Laid-Open No. 2001-283470

[Disclosure of Invention]

[Problems to be Solved by the Invention]

[0006]

In the case of conventional optical disks on which contents data is recorded, however, in the event of printing of visual information on the label surface by inkjet, the recording medium

has to be manufactured such that printable label surface is preformed thereon. In addition, in the event of recording of visual information on a data recording surface with laser, since the surface on which the visual information is formed is used as the data recording surface, problems are not only that the visual information cannot be easily recognized, but also that, when there is not a free area available, the visual information cannot be sufficiently recorded.

[0007]

The present invention has been made in view of the respective problems described above, one example of objects of the invention is to provide an optical disk manufacturable by a conventional recording medium manufacturing method and recordable by an information recording apparatus for use in recording on a conventional recording medium, and to provide a data recording apparatus for recording contents data on the optical disk.

[Means for Solving the Problems]

[0008]

In order to solve the above problems, the invention of claim 1 relates to an optical recording medium, characterized by comprising:

a data recording layer on which contents data is recorded by irradiation of an optical beam, and

a visual information recording layer on which visual information which is visually recognized and indicative of

information regarding the contents of the contents data is recorded by irradiation of the optical beam,

wherein the data recording layer and the visual information recording layer are laminated.

[0009]

In order to solve the above problems, the invention of claim 9 relates to a data recording apparatus that records visual information onto an optical recording medium formed by lamination of a data recording layer onto which contents data is recorded, and a visual information recording layer on which visual information which is visually recognized and indicative of information regarding the contents of the contents data is recorded,

the data recording apparatus being characterized by comprising:

an interface that inputs the visual information to be recorded;

a pickup that is used to record the input visual information; and

a visual-information dedicated drive signal generating device that generates a visual-information dedicated drive signal for driving the pickup in accordance with the input visual information,

wherein the pickup records the visual information onto the visual information recording layer in accordance with the generated visual-information dedicated drive signal.

[Best Mode for Carrying Out the Invention]

[0010]

Now, preferred embodiments of the present invention will be described hereinbelow with reference to the drawings.

[0011]

Embodiments described below are each in the case where an optical recording medium of the invention and a data recording apparatus of the invention for recording data onto the optical recording medium are adapted to an optical disk for recording contents data, for example, a DVD-R or DVD-RW device, and to a data recording and playback apparatus for recording contents data and visual information onto the optical disk.

[0012]

(First Embodiment)

First, a first embodiment of an optical disk and data recording and a playback apparatus will be described hereinbelow with reference to FIGS. 1 to 5.

[0013]

To begin with, a physical structure and a data structure of the optical disk in the present embodiment will be described with reference to FIGS. 1 to 3.

[0014]

Fig. 1 is a view showing the physical structure of the optical disk of the present embodiment, and FIG. 2 is a view showing the data structure of the optical disk of the present embodiment.

[0015]

FIG. 3 is one example of the optical disk when visual information is recorded thereon in the first embodiment.

[0016]

With reference to FIG. 1, an optical disk 100 has a structure formed by bonding a first substrate 110 and a second substrate 120. On the first substrate there is provided a recording layer ("data recording apparatus", hereafter) for recording contents data. On the second substrate there is provided a recording layer ("visual information recording layer", hereafter) for recording visually recognizable information, such as information on the contents of contents data or a title of the contents data, as visual information.

[0017]

The first substrate 110 is provided with a data recording layer provided on the side of the second substrate 120 and is formed of a transparent material permeable to the laser. The first substrate 110 is formed on the data recording surface that irradiated with the laser light.

[0018]

More specifically, the first substrate 110 is provided with the data recording layer formed of a phase change film that changes the reflectance by using the crystallized condition of a substance, thereby to record the contents data and other data by changing the reflectance of the phase change film.

[0019]

The second substrate 120 is provided with a visual information recording layer provided on the side of the first

substrate 110 and is formed of a transparent material permeable to the laser, similarly as the first substrate 110. The first substrate 110 is formed on the label surface on the side opposite to the data recording surface.

[0020]

More specifically, the second substrate 120 is provided with the visual information recording layer that contains dyes different from one another in reflectance depending on irradiation of the laser light. An example of the film is a film that has characteristics in which high reflection light energy is produced and the reflection light energy reduces upon irradiation of the laser light.

[0021]

The optical disk 100, which has the physical structure described above, has a data structure shown in FIG. 2. On the recording layer formed on the first substrate 110, there are, in order from the inner periphery side, a clamp hole 111 for fixing the optical disk 100 to a spindle of a spindle motor (not shown) of a playback apparatus for performing playback of the optical disk 100; a first non-recording area 112 used to fix the disk; a recording information area 113 for adjusting the laser light in the event of writing of contents data; a first read-in area 114 recording management information for being used to manage or control recording and playback of the contents data; a data area 115 for recording the contents data; and a read-out area 116 for recording various types of information for being used for information recording termination and information

playback termination.

[0022]

For example, the first read-in area 114 of the present embodiment constitutes a data management area of the present invention, and the data area 115 constitutes a data recording area of the present invention.

[0023]

More specifically, in the recording information area 113 there are provided, for example, an area (PCA: power calibration area) for intensity compensation for optical beams in the event of recording of information on the optical disk 100, and an area (RMA: recording management area) use to record recording management information necessary for a data recording and playback apparatus 200.

[0024]

The first read-in area 114 contains items of preliminarily recorded information, that is, identification information of the optical disk 100; substrate information indicating that the surface of the optical disk 100 to be irradiated by the laser light is the digital recording; address management information regarding the address used to specify the data area 115; and other information such as management information regarding the copyright protection of the recorded contents data.

[0025]

In the first read-in area 114, the data area 115, and the read-out area 116, a groove-shaped tracks ("groove tracks", hereafter) for recording data, and tracks ("land tracks",

hereafter) having a different height from the groove tracks each interposed between the groove tracks are formed. The groove tracks and the land tracks are spirally formed adjacent to one another from the inner periphery side to the outer periphery side.

[0026]

In the respective areas, the groove tracks are formed of grooves each called a "wobble" meandering at a certain cycle (the groove hereafter will be referred to as a "groove wobble"). In these areas, there are stored ether signals for tracking of an optical pickup 201 and signals for rotation control of the optical disk 100, or information such as pre-pit detection gate signals to be used for playback control or recording control of the optical disk 100 in the data playback apparatus in the event of playing back the contents data in accordance with the wobble signals occurred by the groove wobbles.

[0027]

Further, in these areas, there are sequentially recorded respective items of data, such as the contents data, in the direction from of the inner periphery side to the outer periphery side.

[0028]

On the land tracks formed in the respective areas, there are regularly prestored pits containing address information indicative of the positions in the optical disk 100 (the pits hereafter will be referred to as "land pre-pits"), and pits indicative that the second substrate 120 has a visual information

area 123 for recording the visual information.

[0029]

In or on the visual information recording layer provided on the second substrate 120, there are formed, in order from the inner periphery side, the clamp hole 111, a second non-recording area 121 for the fixation, a second read-in area 122 for recording management information for being used to manage records in the event of recording of the visual information and a visual information area 123 for recording the visual information.

[0030]

The second read-in area 122 of the present embodiment constitutes, for example, a visual information management area of the present invention.

[0031]

More specifically, in the second read-in area 122, there are recorded items of information which follow, in addition to the identification information of the optical disk 100. The items of information are substrate information indicative that the surface of the optical disk 100 to be irradiated with the laser light is the visual information recording layer; address management information regarding the address specifying the visual information area 123; and visual information management information for being used to determine whether or not visual information is already recorded. Further, in the second read-in area 122, there is recorded visual-information contents information that is indicative of the contents of visual

information after the visual information has been recorded and that is indicative of information of an address at which the visual information has been recorded.

[0032]

In the visual information area 123, there is recorded visual information to be visually transferred to a user, and data that, even when data in that portion is read by the pickup 201, does not constitute data having significance as contents data.

[0033]

For instance, suppose that, as shown in FIG. 3A and 3B, contents data of a 12th series version of a drama--drama title "ABC", broadcast date "2003/8/20" or a 13th series version of the drama, broadcast date 2003/8/27, is stored in the data area 115. In this case, visual information indicative of the contents of the contents data is recorded onto the visual information recording layer.

[0034]

In more specific, FIG. 3B shows a recordable optical disk 100, such as a DVD-R, in which the visual information is indicated in the event that the 13th series version of the "ABC" drama is additionally indicated to the description of the 12 series version of the "ABC" drama.

[0035]

As shown in FIG. 3B, in the case that the contents data of the 13th series version of the "ABC" drama additionally written into the optical disk 100 and the contents data of the 12th series

version of the "ABC" drama is unnecessary, the visual information thereof can be added with a cancellation line being added on. In this case, the contents data of the 12th series version of the "ABC" drama is physically undeletable because the medium is the recordable optical disk 100. However, management is carried out in accordance with contents management information and other information recorded in the first read-in area 114 so that the contents data is virtually deleted, that is, the contents data is inhibited from being read out.

[0036]

In addition, as described further below, according to the present embodiment, when the data recording and playback apparatus 200 has read out the visual-information contents information, the data recording and playback apparatus 200 is able to acquire, as information, the structure of the visual information stored in the optical disk 100.

[0037]

Similarly as in the first substrate 110, in the second read-in area 122 and the visual information area 123, groove-shaped groove tracks for recording data and land tracks each interposed between the groove tracks are formed, and the groove tracks and the land tracks spirally formed adjacent to one another from the inner periphery side to the outer periphery side.

[0038]

Similarly as in the first substrate 110, in the second read-in area 122, data is sequentially recorded onto the groove

tracks from the inner periphery side; however, as described further below, in the visual information area 123, visual information is randomly recorded onto the respective groove tracks and land tracks.

[0039]

With reference to FIG. 4, the data recording and playback apparatus for recording contents data and visual information onto the optical disk will be described hereinbelow.

[0040]

FIG. 4 is a block diagram showing the configuration of the data recording and playback apparatus that records contents data and visual information onto the optical disk of the present embodiment.

[0041]

With reference to FIG. 4, either contents data or visual information output from a personal computer 50 connected as an external device is input into the data recording and playback apparatus 200. The data recording and playback apparatus 200 records the input contents data or visual information onto the optical disk 100.

[0042]

In the present embodiment, contents data and visual information to be recorded are generated by an application program running in the personal computer 50. The data recording and playback apparatus 200 records onto the optical disk 100 the contents data and visual information thus generated as data to be recorded.

[0043]

More specifically, the data recording and playback apparatus 200 is configured to include the pickup 201 that activates a semiconductor laser in accordance with the input contents data or visual information. In this configuration, the pickup 201 is used to irradiate a laser beam on either the data recording layer or visual information recording layer of the optical disk 100. With the laser beam irradiated on the optical disk 100, recording and playback of the contents data and recording of visual information are performed on the optical disk 100.

[0044]

The data recording and playback apparatus 200 is connected to external devices, such as the personal computer 50, and is configured to include an interface 202 that is used for either input and output of contents data or input of visual information; an input and output management unit 203 that manages contents data and visual information; a data recording encoder 204 that encodes the input contents data into a predetermined format for recording the data on the optical disk 100; a visual information recording encoder 205 that converts the input visual information into a predetermined format for recording the information onto the optical disk 100; a drive shift control unit 206 that shifts a drive waveform of the pickup 201; a decoder 207 that decodes a signal read out by the pickup 201 into a predetermined format; a data recording RAM 208 that is used either to record or to read out contents data; a visual information recording RAM 209

that is used to record visual information; and a system control unit 210 that totally controls the respective component units described above while performing supply and/or reception of necessary control information through a bus 211. The respective units are connected to one another via the bus 211.

[0045]

For example, the data recording encoder 204 of the present embodiment constitutes contents-data dedicated drive signal generating device of the present invention, and the visual information recording encoder 205 of the present embodiment constitutes visual-information dedicated drive signal generating device of the present invention.

[0046]

In addition, for example, the drive shift control unit 206 of the present embodiment constitutes selecting device of the present invention, and the system control unit 210 of the present embodiment constitutes detecting device and determining device of the present invention.

[0047]

When recording contents data and visual information onto the optical disk 100, the pickup 201 operates in accordance with a modulated signal generated by the data recording encoder 204 and the visual information recording encoder 205.

[0048]

More specifically, in accordance with the modulated signal generated by the data recording encoder 204 and the visual information recording encoder 205, the pickup 201 causes

activation of the semiconductor laser (not shown) provided in the pickup 201, and causes emanation of a laser beam to the optical disk 100. The laser beam varies in intensity corresponding to information being recorded.

[0049]

In addition, the pickup 201 emanates a laser beam of a fixed intensity for playback, receives reflected light thereof through a light receiver unit (not shown), generates a detection signal variable corresponding to intensity variation of reflected light, and outputs the generated detection signal to the decoder 207.

[0050]

The interface 202 inputs either contents data having a predetermined format or visual information from the outside. The interface 202 converts the input contents data or visual information into a predetermined format and then outputs them to the input and output management unit 203.

[0051]

In addition, contents data read out by the pickup 201 from the optical disk 100 is input from the input and output management unit 203 into the interface 202. In accordance with an instruction of the system control unit 210, the interface 202 outputs the input contents data to the personal computer 50 connected to the outside through the interface 202.

[0052]

The input and output management unit 203 inputs either the contents data or visual information converted by the

interface 202 into the predetermined format. In accordance with an instruction of the system control unit 210, the input and output management unit 203 uses the data recording RAM 208 to output the input contents data to the data recording encoder 204 and to output the input visual information to the visual information recording encoder 205.

[0053]

In addition, the input and output management unit 203 inputs contents data decoded by the decoder 207 and read out from the optical disk 100. Similarly as in the case of input of the contents data, the input and output management unit 203 uses the data recording RAM 208 to output the contents data, which has been output from the decoder 207, to the personal computer 50 connected to the outside through the interface 202.

[0054]

More specifically, while temporarily storing input contents data into the data recording RAM 208, the input and output management unit 203 reads out contents data from the data recording RAM 208 with a predetermined timing, and outputs the contents data to either the data recording encoder 204 or the interface 202.

[0055]

In addition, similarly as in the case of the contents data, while temporarily storing the output visual information into the visual information recording RAM 209, the input and output management unit 203 reads out visual information from the visual information recording RAM 209 with a predetermined timing, and

outputs the visual information to the visual information recording encoder 205.

[0056]

The data recording encoder 204 inputs contents data through the input and output management unit 203. In accordance with an instruction of the system control unit 210, the data recording encoder 204 performs a predetermined process on input contents data, generates modulated signal for use in writing onto the optical disk 100, and outputs the generated modulated signal to the drive shift control unit 206.

[0057]

More specifically, the data recording encoder 204 includes a signal processor unit 204a that performs error correction encoding of the input contents data and that adds an error correction signal of, for example, an ECC (error checking and correcting) block; and encoding processor unit 204b that performs an 8/16 modulation (Eight to Fourteen Modulation) of the contents data added with the error correction signal, in accordance with predetermined encoding rules or standards, thereby to generate a modulated signal.

[0058]

The visual information recording encoder 205 inputs visual information output from the input and output management unit 203 through the visual information recording RAM 209. In accordance with an instruction of the system control unit 210, the visual information recording encoder 205 performs a predetermined process on the input visual information to thereby

generate a modulated signal for use in writing onto the optical disk 100, and outputs the generated modulated signal to the drive shift control unit 206.

[0059]

More specifically, the visual information recording encoder 205 acquires visual information once written from the visual information recording RAM 209, and generates a modulated signal for adjusting from the laser beam intensity corresponding to the contrast in accordance with the acquired visual information.

[0060]

In addition, in accordance with an address on the optical disk 100 acquired by the decoder 207 described further below, the visual information recording encoder 205 determines a recording position, i.e., an address, of the modulated signal generated through the system control unit 210, and outputs the modulated signal generated in accordance with the determined address.

[0061]

Further, after recording of the visual information, the visual information recording encoder 205 controls the pickup 201 to write address information of the recorded area, i.e., the range having recorded visual information, in the second read-in area 122. Concurrently, the encoder generates a modulated signal corresponding to the address information and outputs the information to the drive shift control unit 206.

[0062]

The drive shift control unit 206 inputs the modulated signals output from the data recording encoder 204 and the visual information recording encoder 205. In accordance with an instruction of the system control unit 210, the drive shift control unit 206 selects any one of the input modulated signals, and outputs the selected modulated signal to the pickup 201.

[0063]

More specifically, the drive shift control unit 206 selects the modulated signal output from the data recording encoder 204 in the event of recording of contents data onto the optical disk 100, and selects the modulated signal output from the visual information recording encoder 205 in the event of recording of visual information onto the optical disk 100, and outputs the selected modulated signal to the optical pickup 201.

[0064]

The decoder 207 inputs the detection signal detected by the pickup 201. The decoder 207 performs predetermined processes, such as preset amplification process and waveform shaping process, on the detected detection signal. In addition, the decoder performs a preset demodulation process, thereby to generate various types of information, such as identification information of the optical disk 100, visual information management information, substrate information and address management information recorded in the respective read-in areas; contents data; and address information recorded in the land pre-pits.

[0065]

In addition, the decoder 207 outputs the various types of generated information to either the input and output management unit 203 or the system control unit 210.

[0066]

The system control unit 210 is, primarily, configured to include a central processing unit ("CPU", hereafter) and memory, and totally controls the data recording and playback apparatus 200 in accordance with instructions of the personal computer 50 connected to the outside. In more specific, the system control unit 210 controls the respective units in the event of recording either contents data or visual information, and the respective units in the event of recording of contents data and playback thereof.

[0067]

As described above, according to the present embodiment, the contents data and visual information to be recorded are generated by the application program running in the personal computer 50. In accordance with the instructions of the personal computer 50 input through the bus 211 and the like, the system control unit 210 controls the respective units, and records onto the optical disk 100 contents data and visual information generated as data to be recorded.

[0068]

In addition, in the event of recording of contents data or playback thereof and in the event of recording of visual information, the system control unit 210 acquires, through the pickup 201 and the decoder 207, identification information of

the optical disk 100, visual information management information, various types of information such as substrate information and address management information, and predetermined information such as visual information management information recorded in the first read-in area 114 and the second read-in area 122; and address information recorded in the land pre-pits.

[0069]

Especially, as described further below, in the event of an initial operation of recording visual information, the system control unit 210 acquires predetermined information in either the first read-in area 114 or the second read-in area 122, possibility/impossibility of recording visual information onto the substrate irradiated with the laser beam, and the recording position in the visual information area 123. In addition, while acquiring address information stored in the land pre-pits in the event of recording of the visual information onto the optical disk 100, the system control unit 210 records the visual information onto the optical disk 100 in accordance with the address information and the other information.

[0070]

More specifically, in the event of a rewritable optical disk 100, such as a DVD-RW device, in accordance with the acquired address recorded onto the optical disk 100, the system control unit 210 causes the intensity of the laser beam to be adjusted by the pickup 201, and concurrently controls the pickup to irradiate the laser beam onto the optical disk 100 and to record the visual information thereon.

[0071]

Similarly, also when rewriting visual information onto the rewritable optical disk 100 on which visual information has already been recorded, the system control unit 100 erases the visual information recorded with the laser beam, and concurrently records the new visual information.

[0072]

Alternatively, in the event of a recordable optical disk 100, such as a DVD-R device, in accordance with an acquired address recorded onto the optical disk 100, the system control unit 210 causes the laser beam emanated from the pickup 201 to irradiate only on the visual information area 123 corresponding to the address portion to be irradiated, thereby causing the visual information to be recorded.

[0073]

In the event that adding the visual information to the optical disk 100 on which visual information has already been recorded, the system control unit 100 operates in accordance with visual information management information so that an unirradiated address portion is recognized, as shown in Fig. 3B, the unirradiated address portion is irradiated, and visual information management information in the recorded visual information is added to the already recorded visual information management information, whereby additional writing is carried out.

[0074]

In addition, in accordance with the visual information

management information, the system control unit 210 forms the structure of visual information recorded onto the optical disk 100, that is, a record pattern of the recorded visual information, and outputs the formed record pattern of the visual information to an external device, such as the connected personal computer 50.

[0075]

More specifically, in the event that visual information has been recorded with visual information management information, the system control unit 210 acquires an address at which the laser beam has been irradiated, and forms the record pattern of the visual information in accordance with the acquired address.

[0076]

Details of recording processes for visual information in the system control unit 210 of the present embodiment will be described below.

[0077]

Operation of the recording processes for visual information in the system control unit will be described with reference to FIGS. 5 and 6.

[0078]

FIG. 5 is a flowchart showing a recording process of the system control unit for visual information in a rewritable optical disk. FIG. 6 is a flowchart showing a recording process of the system control unit for visual information in a recordable optical disk.

[0079]

The operation of the recording processes will be described separately in the event of a rewritable optical disk such as a DVD-RW device allowing overwrite of data and in the event of a recordable optical disk such as a DVD-R device allowing only one-time recording or additional writing thereto.

[0080]

For the operation, the case is now assumed such that the optical disk 100 for recording the visual information is already set on the data recording and playback apparatus 200. Concurrently, the identification between the rewritable optical disk 100 and the recordable optical disk 100 are already performed in accordance with various types of information stored in either the first read-in area 114 or the second read-in area 122.

[0081]

(Rewritable Optical Disk)

With reference to FIG. 5, with an application program being activated, in system control unit 210, input is carried out specifying to record visual information output from the personal computer 50 onto the rewritable disk (step S11). Responsively, the system control unit 210 controls the pickup 201, thereby reading out various types of information. They are, for example, substrate information, address management information, and visual information management information, if recorded, from either one of the first read-in area 114 and second read-in area 122 of the optical disk 100, that is, from a read-in area existing on the surface readable by the pickup 201 (step S12).

[0082]

More specifically, the system control unit 210 drives a drive unit (not shown) of the pickup, thereby causing the pickup 201 to search the read-in area. In addition, the system control unit controls a spindle motor (not shown) to rotate the rewritable optical disk 100, thereby causing the pickup 201 to read out the various types of information recorded in the read-in area, whereby to acquire the read out the various types of information through the decoder 207.

[0083]

Subsequently, the system control unit 210 determines in accordance with the acquired substrate information whether or not the surface of the optical disk 100 recordable by the pickup 201 is a visual information recording surface (step S13).

[0084]

If having determined that the surface recordable by the pickup 201 is the data recording surface, the system control unit 210 sends a notification to that effect to the personal computer 50 (step S14), and then terminates the operation.

[0085]

In this event, if the personal computer 50 has received a notification to the effect that the surface recordable by the pickup 201 is the data recording surface, since the visual information cannot be recorded onto the data recording surface, the personal computer 50 notifies the user to that effect through a display or speaker connected to the personal computer 50.

[0086]

Alternately, if having determined that the surface recordable by the pickup 201 is the visual information recording surface, then the system control unit 210 determines in accordance with the acquired visual information management information whether or not visual information has already been recorded on the optical disk 100 (step S15).

[0087]

If having determined that visual information has not yet been recorded on the optical disk 100, then the system control unit 210 outputs a notification to that effect to the personal computer 50, and awaits input of visual information to be recorded (step S16).

[0088]

Alternatively, if having determined that visual information has already been recorded on the optical disk 100, then the system control unit 210 reads out the visual information, outputs the read out visual information with a notification to that effect to the personal computer 50, and awaits input of visual information to be recorded (step S17).

[0089]

More specifically, if having determined that visual information has already been recorded on the optical disk 100, then the system control unit 210 controls the pickup 201, thereby to cause visual information management information recorded in the second read-in area 122 to be read. Then, the system control unit causes a record pattern of the visual information to be formed in accordance with the read out visual information

management information, and causes the formed visual information to be output to the computer.

[0090]

If, at steps S16 and S17, having received the notification to the effect that visual information is not yet recorded on the optical disk 100 set on the data recording and playback apparatus 200, then the personal computer 50 displays a disk surface of a new optical disk 100 in accordance with the application program. Alternatively, if having received the notification to the effect that visual information has already been recorded on the optical disk 100 set on the data recording and playback apparatus 200, the personal computer 50 displays a record pattern of the received visual information, that is, a formed record pattern of the visual information, in accordance with the application program.

[0091]

Subsequently, the visual information being recorded on the optical disk 100 is edited or generated by the personal computer 50, and input is carried out to specify execution of recording of the visual information onto the optical disk 100 (step S18). Then, the system control unit 210 controls the drive shift control unit 206 to shift a signal input of the pickup 201 to the visual information recording encoder 205. In addition, the system control unit controls the drive unit (not shown) of the pickup 201 to search the surface to the recording position of the visual information, that is, to the innermost peripheral position of the visual information area 123 (step S19).

[0092]

Subsequently, when visual information to be recorded is input into the data recording and playback apparatus 200 from the personal computer 50, then the visual information to be recorded is input into the visual information recording encoder 205 through the input and output management unit 203 and the visual information recording RAM 209. Then, the visual information recording encoder 205 controls the pickup 201 in accordance with the input visual information, thereby recording the input visual information onto the optical disk 100 (step S20).

[0093]

More specifically, the input and output management unit 203 outputs the input visual information to the visual information recording RAM 209 through the interface 202. Concurrently, the visual information recording encoder 205 generates a modulated signal from the visual information input through the visual information recording RAM 209.

[0094]

In addition, while determining address information in accordance with the input visual information and controlling the position of the pickup 201 through the system control unit 210 in accordance with the determined address information and the address on the optical disk 100 for recording the visual information read out by the decoder 207, the visual information recording encoder 205 outputs the modulated signal to the pickup 201.

[0095]

Finally, when input is carried out from the personal computer 50 to specify termination of recording of visual information, then the system control unit 210 causes the visual information recording encoder 205 to generate visual information management information, and causes the generated visual information management information to be recorded through the pickup 201 in a predetermined area of the second read-in area 122 (step S21).

[0096]

More specifically, the system control unit 210 causes the address irradiated or not irradiated with the laser beam to be overwritten to the second read-in area 122 as visual information management information in the formed visual information.

[0097]

(Recordable Optical Disk)

With reference to FIG. 6, with an application program being activated, in system control unit 210, input is carried out specifying to record visual information output from the personal computer 50 onto the recordable disk (step S31). Responsively, the system control unit 210 reads out various types of information, such as substrate information, from either one of the first read-in area 114 and second read-in area 122 of the optical disk 100 (step S32).

[0098]

Subsequently, the system control unit 210 determines in accordance with the acquired substrate information whether or

not the surface of the optical disk 100 recordable by the pickup 201 is a visual information recording surface (step S33).

[0099]

If having determined that the surface recordable by the pickup 201 is the data recording surface, the system control unit 210 sends a notification to that effect to the personal computer 50 (step S34), and then terminates the operation.

[0100]

Alternately, if having determined that the surface recordable by the pickup 201 is the visual information recording surface, then the system control unit 210 determines in accordance with the acquired visual information management information whether or not visual information has already been recorded on the optical disk 100 (step S35).

[0101]

If having determined that visual information is not yet recorded on the optical disk 100, then the system control unit 210 outputs a notification to that effect to the personal computer 50, and awaits input of visual information to be recorded (step S36).

[0102]

Alternatively, if having determined that visual information has already been recorded on the optical disk 100, then the system control unit 210 determines in accordance with the acquired visual information management information the presence or absence of a recordable area (step S37). If having determined that the recordable area is not present, the system

control unit 210 outputs a notification to that effect to the personal computer 50 (step S38), and terminates the operation.

[0103]

In this event, if the personal computer 50 has received a notification to the effect that the visual information area 123 capable of recording the visual information, since the visual information cannot be recorded onto the data recording surface, the personal computer 50 notifies the user to that effect through a display or speaker connected to the personal computer 50.

[0104]

Alternately, if having determined that the recordable visual information area 123 is present, then the system control unit 210 reads out the recorded visual information, outputs the visual information with a notification to that effect to the personal computer 50, and awaits input of visual information to be recorded (step S39).

[0105]

More specifically, if having determined that visual information has already been recorded on the optical disk 100, then, similarly as in the case of the rewritable optical disk 100, the system control unit 210 controls the pickup 201, thereby to cause readout of newest visual information management information recorded in the second read-in area 122. Then, the system control unit causes visual information to be formed in accordance with the read out visual information management information, and causes the formed visual information to be output to the computer.

[0106]

If, at steps S36 and S37, having received the notification to the effect that visual information is not yet recorded on the optical disk 100 set on the data recording and playback apparatus 200, then the personal computer 50 displays a disk surface of a new optical disk 100 in accordance with the application program. Alternatively, if having received the notification to the effect that visual information has already been recorded on the optical disk 100 set on the data recording and playback apparatus 200, then the personal computer 50 displays a record pattern of the received visual information, that is, a formed record pattern of the visual information, in accordance with the application program.

[0107]

Subsequently, the visual information being recorded on the optical disk 100 is edited or generated by the personal computer 50, and input is carried out to the system control unit 210 to specify execution of recording of the visual information onto the optical disk 100 (step S40). Then, the system control unit 210 controls the drive shift control unit 206 to shift a signal input of the pickup 201 to the visual information recording encoder 205. In addition, the system control unit controls the drive unit (not shown) of the pickup 201 to search the surface to the recording position of the visual information (step S41).

[0108]

Subsequently, when visual information to be recorded is input into the data recording and playback apparatus 200 from

the personal computer 50, then the visual information to be recorded is input into the visual information recording encoder 205 through the interface 202, the input and output management unit 203 and the visual information recording RAM 209. Then, the visual information recording encoder 205 controls the pickup 201 in accordance with the input visual information, thereby recording the input visual information onto the optical disk 100 (step S42).

[0109]

Finally, when input is carried out from the personal computer 50 to specify termination of recording of visual information, then the system control unit 210 causes the visual information recording encoder 205 to generate visual information management information, and causes the generated visual information management information to be recorded through the pickup 201 in a predetermined area of the second read-in area 122 (step S43).

[0110]

More specifically, the system control unit 210 causes the address irradiated or not irradiated with the laser beam to be overwritten to the second read-in area 122 as new visual information management information in the formed visual information.

[0111]

Thus, according to the present embodiment, the optical disk 100 includes the data recording layer on which contents data is recorded by irradiation of the laser beam, and the visual

information recording layer on which the visual information which is visually recognized and indicative of information regarding the contents data is recorded by irradiation of the laser beam. The data recording layer and the visual information recording layer are laminated.

[0112]

With this structure, according to the present embodiment, when the visual information is recorded to be visually recognized from the surface different from the data recording surface through which the data recording layer is irradiated with the laser beam, identifiable and visual information can easily and accurately be formed in units of the optical disk 100.

[0113]

Accordingly the management can easily be done for a plurality of optical disks 100 that each enable characters, symbols, and/or other markings to be easily and accurately indicated, compared to the case of handwriting characters, symbols, and/or other markings indicative of the contents of the contents data.

[0114]

Further, according to the present embodiment, in the case that the structure is thus formed to include the data recording layer and visual information recording layer respectively provided by being laminated, the structure is the same as that of the conventional optical disk 100. The optical disk 100 of the present embodiment, therefore, can be manufactured by a manufacturing method for the conventional optical disk 100, so

that the manufacturing cost for the optical disk 100 can be reduced, and low cost optical disks 100 can be provided.

[0115]

Further, according to the present embodiment, the optical disk 100 is structured such that, the visual information is recorded onto the visual information recording layer by irradiation of the laser beam, which is visually recognized from the surface different from the data recording surface through which the data recording layer is irradiated with the laser beam.

[0116]

With this structure, according to the present embodiment, the visual information can be indicated onto the different surface of the data recording surface, that is the surface on which the contents data is not recorded, for example, in the case that the contents data is recorded only onto a single surface. As such, when managing a plurality of optical disks 100, the optical disks 100 can be accurately identified from one another, therefore making it possible to improve the usability for users.

[0117]

According to the present embodiment, the structure is formed such that the visual information is recorded onto the visual information recording layer by irradiation of the laser beam from the surface different from the data recording surface.

[0118]

With such a structure, in the present embodiment, the visual information is recorded by irradiation of the laser beam from the surface different from the data recording surface.

Accordingly, when the contents data is recorded only onto the single surface, for instance, the visual information is indicated on the surface onto which the contents data is not recorded. As such, when managing a plurality of optical disks 100, the optical disks 100 can be accurately identified from one another, consequently making it possible to improve the usability for users.

[0119]

Further, according to the present embodiment, the optical disk 100 has the structure in which the data recording layer is provided on the first substrate 110 and the visual information area 123 is provided on the second substrate 120, so that the structure is the same as that of the conventional optical disk 100. The optical disk 100 of the present embodiment, therefore, can be manufactured by the manufacturing method for the conventional optical disk 100. Consequently, the manufacturing cost for the optical disk 100 can be reduced, and low cost optical disks 100 can be provided.

[0120]

Further, according to the present embodiment, on the visual information recording layer there are provided the visual information area 123 for recording the visual information; and the second read-in area 122 in which the substrate information indicative of the visual information recording layer, the visual information management information indicative of the presence or absence of the record of the visual information, and the address management information indicative of the recordable area for

visual information are recorded.

[0121]

With this structure, in the present embodiment, readout of the various types of data recorded in the second read-in area 122 makes it possible to determine the possibility/impossibility of recording onto the optical disk 100 currently being irradiated with the laser beam, the propriety of the visual information recording surface on the surface of the optical disk 100, and the area on which visual information can be recorded. Consequently, visual information can be accurately and easily recorded onto the optical disk 100.

[0122]

Further, according to the present embodiment, the structure is formed such that, the visual information area 123 in which the substrate information indicative that the visual information recording layer is regularly recorded is provided on the visual information recording layer.

[0123]

With this structure, in the present embodiment, even when the visual information area 123 has been searched by the pickup 201, it is possible to recognize that the optical disk 100 is provided with the visual information area 123.

[0124]

Further, according to the present embodiment, on the data recording layer are provided the data recording area for recording the contents data; the first read-in area 114 in which at least one of the recording layer information indicative that

the recording layer is the corresponding data recording layer, and recording medium information indicative that the visual information recording layer is provided on the optical recording medium.

[0125]

According to the present embodiment, with the structure described immediately above, readout of the various types of data information recorded in the first read-in area makes it possible to determine the possibility/impossibility of recording visual information onto the optical disk 100 currently being irradiated with the laser beam and the propriety of the visual information recording surface on the surface of the optical disk 100. Consequently, visual information can be accurately and easily recorded onto the optical disk 100.

[0126]

Further, according to the present embodiment, the data recording and playback apparatus 200 has the configuration that records visual information onto an optical disk 100 formed by lamination of the data recording layer onto which the contents data is recorded, and a visual information recording layer on which visual information which is visually recognized and indicative of information regarding the contents of the contents data is recorded. The configuration includes the interface 202 that inputs visual information to be recorded; the pickup 201 that is used to record the input visual information; and the visual information recording encoder 205 that generates the visual-information dedicated modulated signal for driving the

pickup 201, in accordance with the input visual information. The pickup 201 records the visual information onto the visual information recording layer in accordance with the generated visual-information dedicated modulated signal.

[0127]

With this configuration, in the present embodiment, the modulated signal for driving the pickup 201 is generated in accordance with the input visual information, and the visual information is recorded onto the visual information recording layer in accordance with the visual-information dedicated modulated signal.

[0128]

Accordingly, in the present embodiment, when the visual information is recorded onto the optical disk 100 to be visually recognized from the surface different from the data recording surface which is the surface through which the data recording layer is irradiated with the laser beam, identifiable and visual information can easily and accurately be formed in units of the optical disk 100.

[0129]

Consequently, the management can easily be done for a plurality of optical disks 100 that each enable characters, symbols, and/or other markings to be easily and accurately indicated, compared to the case of handwriting of characters, symbols, and/or other markings indicative of the contents of contents data.

[0130]

Further, according to the present embodiment, when the visual information is recorded onto the optical disk 100 formed to include the data recording layer and visual information recording layer respectively provided by being laminated, the structure is the same as that of the conventional optical disk 100. The visual information, therefore, can be recorded onto the optical disk 100 that can be manufactured by a manufacturing method for the conventional optical disk 100.

[0131]

Further, in the present embodiment, the configuration includes the data recording encoder 204 that, when the contents data is input into the interface 202 and the interface 202 records the contents data onto the data recording layer, generates a contents-data dedicated modulated signal for driving the pickup 201, in accordance with the input visual information; and the drive shift control unit 206 that selects one of the contents-data dedicated modulated signal and the visual-information dedicated modulated signal generated by the visual information recording encoder 205. When the contents-data dedicated modulated signal is selected, the pickup 201 records the contents data onto the data recording layer in accordance with the contents-data dedicated modulated signal. When the visual-information dedicated modulated signal is selected, the pickup 201 records the contents data in accordance with the visual-information dedicated modulated signal.

[0132]

With this configuration, in the present embodiment, when

the contents-data dedicated modulated signal is selected, the pickup 201 records the contents data onto the data recording layer in accordance with the contents-data dedicated modulated signal. Alternately, when the visual-information dedicated modulated signal is selected, the pickup 201 records the contents data in accordance with the visual-information dedicated modulated signal onto the data recording layer.

[0133]

Accordingly, with the pickup 201, since the contents data and the visual information can be recorded onto the optical disk 100, the data recording and playback apparatus 200 can easily configured, and the data recording and playback apparatus 200 can be provided at low costs.

[0134]

Further, according to the present embodiment, the configuration includes the system control unit 210. In the case that the optical disk 100 includes the visual information recording layer provided with either the second read-in area 122 in which visual information is recorded by irradiation of the laser beam from the surface different from the data recording surface and in which at least substrate information indicative of the corresponding visual information is recorded, or the visual information area 123 in which the visual information and at least substrate information indicative of the corresponding visual information are recorded, the system control unit 210 detects at least one of the substrate information recorded in the second read-in area 122 of the visual information recording

layer and the substrate information recorded in the visual information area 123, and determines an irradiation surface of the optical disk 100 being irradiated with the optical beams in accordance with the detection result.

[0135]

With this configuration, in the present embodiment, there is detected at least one of the substrate information recorded in the second read-in area 122 of the visual information recording layer and the substrate information recorded in the visual information area 123, and there is determined an irradiation surface of the optical disk 100 being irradiated with the optical beams.

[0136]

Accordingly, a surface of the optical disk 100 on which visual information is to be recorded can be accurately and easily verified.

[0137]

Further, according to the present embodiment, the configuration includes the system control unit 210. In the case that the optical disk 100 includes the visual information recording layer on which visual information is recorded by irradiation of the laser beam from the surface different from the data recording surface, and the data recording layer which is provided with the first read-in area 114 in which substrate information indicative of the corresponding data recording layer is recorded, the system control unit 210 detects the substrate information recorded onto the first read-in area 114 of the data

recording layer, and determines a surface of the optical disk 100 being irradiated with the optical beams in accordance with the detection result.

[0138]

With this configuration, in the present embodiment, there is detected the substrate information recorded in the first read-in area 114 of the data recording layer, and there is determined a surface of the optical disk being irradiated with the optical beams.

[0139]

Accordingly, a surface of the optical disk 100 on which visual information is to be recorded can be accurately and easily verified.

[0140]

In the present embodiment, the visual information recording encoder 205 and the data recording encoder 204 are discretely provided. However, the configuration may be such that portions of functions of the encoders are rendered to common, and a shift portion for shifting the signal being input into the pickup 201 is provided in a forestage section where the functions are common, in which the pickup 201 is driven and controlled in accordance with the shifted signal.

[0141]

Further, in the present embodiment, when recording the visual information onto the optical disk 100, visual information is recorded by irradiation of the laser beam from the surface different from the data recording surface. However, the visual

information may be recorded by irradiation of the laser beam from the data recording surface.

[0142]

In this case, the configuration may be such that the system control unit 210 controls the pickup 201 to shift the focal position of the laser beam, whereby recording of the contents data and recording of the visual information are performed. With this configuration, the operation of turning over the surface of the optical disk 100 itself can be omitted.

[0143]

Further, in the present embodiment, the light intensity of the laser beam is varied, and the contrast of the visual information recording layer is increased, thereby to record visual information onto the optical disk 100. However, it may be that the film property is changed, and the visual information recording layer changing in dye depending on the intensity of the laser beam is used, whereby the visual information is recorded onto the optical disk 100.

[0144]

(Second Embodiment)

A second embodiment of a respective optical disk and data recording and playback apparatus will be described hereinbelow with reference to FIG. 7.

[0145]

The present embodiment has features in that dedicated pickups are provided for recording the respective contents data and visual information, in lieu of the manner of recording the

various types of information onto the optical disk by shifting between contents data and visual information by using the single pickup in the first embodiment. Other respects including the configuration of the data recording and playback apparatus and the configuration of the optical disk are similar to those of the first embodiment. As such, like reference numerals are used to represent like units and/or members, and descriptions thereof are omitted here.

[0146]

In addition, according to the present embodiment, in the operation of the recording process, the shift operation of the driving waveform by the drive shift control unit 206 of the first embodiment is not necessary, and the first pickup is used to perform the operation of step S12. Further, according to the present embodiment, at step S13 in the first embodiment, the system control unit 210 determines in accordance with substrate information read out by the first pickup, 301, whether or not the surface recordable by the first pickup 301 is the data recording surface. The other processes are similar to those in the first embodiment, so that descriptions thereof are omitted here.

[0147]

With reference to FIG. 7, the data recording and playback apparatus for recording contents data and visual information onto the optical disk will be described hereinbelow.

[0148]

FIG. 7 is a block diagram showing the configuration of

the data recording and playback apparatus that records contents data and visual information onto the optical disk of the present embodiment.

[0149]

Similarly as in the first embodiment, either contents data or visual information output from the personal computer 50 connected as an external device is input into the data recording and playback apparatus 300. The data recording and playback apparatus 300 records the input contents data or visual information onto the optical disk 100.

[0150]

The data recording and playback apparatus 300 includes a first pickup 301 that drives a semiconductor laser in accordance with the input contents data, and a second pickup 302 that drives a semiconductor laser in accordance with visual information. The respective pickup 201 is used to irradiate the laser beam on either the data recording layer or visual information recording layer of the optical disk 100. With the laser beam thus irradiated on the optical disk 100, recording and playback of the contents data and recording of visual information are performed on the optical disk 100.

[0151]

As shown in FIG. 7, the data recording and playback apparatus 300 is connected to external devices, such as the personal computer 50, and is configured to include an interface 202 that is used for either input and output of contents data or input of visual information; an input and output management

unit 203 that manages contents data and visual information; a data recording encoder 204 that encodes the input contents data into a predetermined format for recording the data on the optical disk 100; a visual information recording encoder 205 that converts the input visual information into a predetermined format for recording the information onto the optical disk 100; a decoder 207 that decodes a signal read out by the pickup 201 into a predetermined format; a data recording RAM 208 that is used either to record or to read out contents data; a visual information recording RAM 209 that is used to record visual information; and a system control unit 210 that totally controls the respective component units described above while performing supply and/or reception of necessary control information through a bus 211. The respective units are connected to one another.

[0152]

For example, the first pickup 301 of the present embodiment constitutes a data recording pickup of the present invention, and the second pickup 302 of the present embodiment constitutes a visual information recording pickup of the present invention.

[0153]

Further, for example, the data recording encoder 204 of the present embodiment constitutes contents-data dedicated drive signal generating device of the present invention, and the visual information recording encoder 205 of the present embodiment constitutes visual-information dedicated drive signal generating device of the present invention.

[0154]

Further, for example, the drive shift control unit 206 of the present embodiment constitutes selecting device of the present invention, and the system control unit 210 of the present embodiment constitutes detecting device and determining device of the present invention.

[0155]

When recording contents data onto the optical disk 100, the first pickup 301 operates in accordance with a modulated signal generated by the data recording encoder 204.

[0156]

More specifically, in accordance with the modulated signal generated by the data recording encoder 204, the first pickup 301 causes driving of the semiconductor laser (not shown) provided in the first pickup 301, and causes emanation of a laser beam to the optical disk 100. The laser beam varies in intensity corresponding to information being recorded.

[0157]

In addition, the first pickup 301 emanates a laser beam of a fixed intensity for playback, receives reflected light thereof through a light receiver unit (not shown), generates a detection signal variable corresponding to intensity variation of reflected light, and outputs the generated detection signal to the decoder 207.

[0158]

The second pickup 302 has similar performance to the first pickup 301. When recording contents data onto the optical disk 100, the second pickup 302 operates in accordance with a modulated

signal generated by the visual information recording encoder 205.

[0159]

More specifically, in accordance with the modulated signal generated by the visual information recording encoder 205, the second pickup 302 causes activation of a semiconductor laser (not shown) provided in the second pickup 302, and causes emanation of a laser beam to the optical disk 100. The laser beam varies in intensity corresponding to information being recorded.

[0160]

In addition, the second pickup 302 emanates a laser beam of a fixed intensity for playback, receives reflected light therefrom through a light receiver unit (not shown), generates a detection signal variable corresponding to intensity variation of reflected light, and outputs the generated detection signal to the decoder 207.

[0161]

Thus, according to the present embodiment, the optical disk 100 includes the data recording layer on which contents data is recorded by irradiation of the laser beam, and the visual information recording layer on which the visual information which is visually recognized and indicative of information regarding the contents data is recorded by irradiation of the laser beam. The data recording layer and the visual information recording layer are laminated.

[0162]

With this structure, according to the present embodiment, when the visual information is recorded to be visually recognized from the surface different from the data recording surface through which the data recording layer is irradiated with the laser beam, identifiable and visual information can easily and accurately be formed in units of the optical disk 100.

[0163]

Accordingly, the management can easily be done for a plurality of optical disks 100 that each enable characters, symbols, and/or other markings to be easily and accurately indicated, compared to the case of handwriting characters, symbols, and/or other markings indicative of the contents of the contents data.

[0164]

Further, according to the present embodiment, in the case that the structure is thus formed to include the data recording layer and visual information recording layer respectively provided by being laminated, the structure is the same as that of the conventional optical disk 100. The optical disk 100 of the present embodiment, therefore, can be manufactured by a manufacturing method for the conventional optical disk 100, so that the manufacturing cost for the optical disk 100 can be reduced, and low cost optical disks 100 can be provided.

[0165]

Further, according to the present embodiment, the optical disk 100 is structured such that, the visual information is recorded onto the visual information recording layer by irradiation of the laser beam, which is visually recognized from the surface different from the data recording surface through which the data recording layer is irradiated with the laser beam.

[0166]

With this structure, according to the present embodiment, the visual information can be indicated onto the different surface of the data recording surface, that is the surface on which the contents data is not recorded, for example, in the case that the contents data is recorded only onto a single surface. As such, when managing a plurality of optical disks 100, the optical disks 100 can be accurately identified from one another, therefore making it possible to improve the usability for users.

[0167]

According to the present embodiment, the structure is formed such that the visual information is recorded onto the visual information recording layer by irradiation of the laser beam from the surface different from the data recording surface.

[0168]

With such a structure, in the present embodiment, the visual information is recorded by irradiation of the laser beam from the surface different from the data recording surface. Accordingly, when the contents data is recorded only onto the

single surface, for instance, the visual information is indicated on the surface onto which the contents data is not recorded. As such, when managing a plurality of optical disks 100, the optical disks 100 can be accurately identified from one another, consequently making it possible to improve the usability for users.

[0169]

Further, according to the present embodiment, the optical disk 100 has the structure in which the data recording layer is provided on the first substrate 110 and the visual information area 123 is provided on the second substrate 120, so that the structure is the same as that of the conventional optical disk 100. The optical disk 100 of the present embodiment, therefore, can be manufactured by the manufacturing method for the conventional optical disk 100. Consequently, the manufacturing cost for the optical disk 100 can be reduced, and low cost optical disks 100 can be provided.

[0170]

Further, according to the present embodiment, on the visual information recording layer there are provided the visual information area 123 for recording the visual information; and the second read-in area 122 in which the substrate information indicative of the visual information recording layer, the visual information management information indicative of the presence or absence of the record of the visual information, and the address

management information indicative of the recordable area for visual information are recorded.

[0171]

With this structure, in the present embodiment, readout of the various types of data recorded in the second read-in area 122 makes it possible to determine the possibility/impossibility of recording onto the optical disk 100 currently being irradiated with the laser beam, the propriety of the visual information recording surface on the surface of the optical disk 100, and the area on which visual information can be recorded. Consequently, visual information can be accurately and easily recorded onto the optical disk 100.

[0172]

Further, according to the present embodiment, the structure is formed such that, the visual information area 123 in which the substrate information indicative that the visual information recording layer is regularly recorded is provided on the visual information recording layer.

[0173]

With this structure, in the present embodiment, even when the visual information area 123 has been searched by the pickup 201, it is possible to recognize that the optical disk 100 is provided with the visual information area 123.

[0174]

Further, according to the present embodiment, on the data

recording layer are provided the data recording area for recording the contents data; the first read-in area 114 in which at least one of the recording layer information indicative that the recording layer is the corresponding data recording layer, and recording medium information indicative that the visual information recording layer is provided on the optical recording medium.

[0175]

According to the present embodiment, with the structure described immediately above, readout of the various types of data information recorded in the first read-in area makes it possible to determine the possibility/impossibility of recording visual information onto the optical disk 100 currently being irradiated with the laser beam and the propriety of the visual information recording surface on the surface of the optical disk 100. Consequently, visual information can be accurately and easily recorded onto the optical disk 100.

[0176]

Further, in the present embodiment, on the data recording layer, there provided the data management area in which at least either one of the recording management information indicative of the presence or absence of the record of visual information and the area information indicative of the recordable area for visual information is recorded.

[0177]

With this structure, in the present embodiment, when, for example, recording respective contents data and visual information onto the optical disk 100 by using the different pickups 201 from different surfaces, readout of the various types of data recorded in the first read-in area 114 existing on the data recording surface makes it possible to determine the possibility/impossibility of recording visual information onto the optical disk 100 currently being irradiated with the laser beam, the propriety of the visual information recording surface on the surface of the optical disk 100, and the area in which visual information can be recorded. Consequently, visual information can be accurately and easily recorded onto the optical disk 100.

[0178]

Although the second pickup 302 of the present embodiment has the equivalent performance to the first pickup 301, accurate recording is not basically necessary for recording visual information. As such, since a light spot to be irradiated with the laser beam may be wide, so that the second pickup 302 may be configured either to have a lower NA (numerical aperture) than the first pickup 301 or to use a semiconductor laser of a long laser-beam wavelength.

[0179]

Accordingly, in this case, with the second pickup 302 irradiating the laser beam with a low NA or with a long-wavelength semiconductor laser, visual information can be quickly recorded in the visual information area 123. In addition, since a low-NA

pickup 302 or a long-wavelength pickup 302 is relatively inexpensive, the data recording and playback apparatus 300 can be provided at a reduced price.

[0180]

According to the present embodiment, in principle, the respective contents data and visual information are discretely recorded onto the data recording layer and the visual information recording layer. However, of course, contents data and visual information may be recorded onto the two respective data recording layer and visual information recording layer by synchronously controlling the respective first and second pickups 301 and 302.

[0181]

Further, in the present embodiment, the substrate information, address management information, visual information management information, and visual-information contents information are recorded in the second read-in area. However, of course, a part or all of the items of data may be recorded in the first read-in area.

[0182]

In this case, these items of data are read out or recorded by the first pickup 301, and the second pickup 302 is controlled by the system control unit 210 in accordance with the respective items of data having been read out.

[Explanation of Reference Numerals]

[0184]

- 110 --- first substrate
- 114 --- first read-in area
- 115 --- data area
- 120 --- second substrate
- 122 --- second read-in area
- 123 --- visual information area
- 200, 300 --- data recording and playback apparatus
- 201 --- pickup
- 204 --- data recording encoder
- 205 --- visual information recording encoder
- 206 --- drive shift control unit
- 210 --- system control unit
- 301 --- first pickup
- 302 --- second pickup

[Name of Document] Abstract

[Abstract]

[Problems to be solved by the Invention]

An object of the invention is to provide an optical disk manufacturable by a manufacturing method of conventional recording medium and that is capable of performing recording with an information recording apparatus used to perform recording on conventional recording mediums, and a data recording apparatus for recording contents data thereon.

[Means for solving the Problems]

As shown in Fig. 1, an optical disk 100 has a structure in which a first substrate 110 and a second substrate 120 are bonded together. The first substrate 110 is provided with a recording layer in which contents data is recorded, and the second substrate 120 is provided with a visual information recording layer in which information enabling visual recognition of, for example, the contents of contents data or a title of the contents data is recorded as visual information.
